The rust responses for Australian wheat and triticale varieties provide growers and technical advisors with updated information to make informed decisions. The varietal responses for wheat and triticale presented in this report are the consensus opinion of Australian cereal pathologists and breeders and are based on the most recent field trial reports as well as previous data sets. They are developed in the context of the prevailing rust pathotypes recorded in 2019 by surveys undertaken by staff at the University of Sydney's Plant Breeding Institute. Gene postulations based on multi-pathotype tests (12 pathotypes each of wheat stripe rust, wheat stem rust, and wheat leaf rust) and pathogen survey results help in explaining regional rust response variation, and in predicting varietal vulnerability to rust. In this issue we have separated the postulated all stage effective resistance (ASR; seedling resistance) and adult plant resistance (APR) genes, and also provide presence/ absence information for the rust resistance genes *Lr34/Yr18/Sr57*, *Lr46/Yr29/Sr58*, *Lr67/Yr46/Sr55*, *Lr37/Yr17/Sr38*, *Lr24/Sr24*, and *Sr2* based on marker genotyping. For each variety showing resistance, the nature of the resistance (ASR or APR) is indicated based on the current occurrence (presence/absence, frequency) and distribution of pathogen virulence. As our knowledge of APR genes in Australian cereal varieties improves, it will be possible to provide more detailed information regarding the genetic basis of APR in varieties and the level of protection the genes confer.

Disease response categories are summarized in **Table 1**. The colour coding in this table has been used in all tables to assist in highlighting strengths and potential weaknesses in varieties with respect to the three rust diseases.

The rust responses of current Australian common wheat, durum wheat and triticale varieties are provided in three sections, the first being for common wheat, the second

for durum wheat, and the third triticale. Within each section there are two to three tables: the first comprises varieties for which NVT consensus ratings were assigned in 2019; additional tables comprise older varieties that while not included in the 2019 NVT testing have been assessed for rust response in the past, or very recent releases for which consensus field rust response ratings are not yet available.

All Stage Resistance (ASR) versus Adult Plant Resistance (APR)

Resistance to rust pathogens in cereals can be expressed at all growth stages from primary leaf emergence onwards (All Stage Resistance (ASR), aka seedling resistance, major gene resistance), or at post seedling growth stages only (Adult Plant Resistance (APR), aka minor gene resistance). Genes conferring both types of resistance occur in Australian wheat, barley and triticale varieties- some varieties carry ASR or APR, others carry both. The identities and effectiveness of most if not all of the ASR genes present in Australian wheat, barley and triticale varieties are well understood. Research on the genetic basis of rust resistance in wheat and barley over the past 25 years has greatly improved our understanding of the genes present that confer APR; these studies have also shown that there are other genes conferring APR that while still uncharacterized are important in protecting against rust infection and hence yield loss. Research by the Australian Cereal Rust Control Program has permitted accurate determination of the presence/absence of the following APR genes in Australian wheat varieties: *Lr34/Yr18/Sr57*, *Lr46/Yr29/Sr58*, *Lr67/Yr46/Sr55* and *Sr2*. Two of these resistances are known to be due to a single gene that confers resistance against all three rust pathogens (*Lr34/Yr18/Sr57* and *Lr67/Yr46/Sr55*), and the resistance *Lr46/Yr29/Sr58* is similarly thought to be due to a single gene. The multiple ASR resistances *Lr37/Yr17/Sr38* and *Lr24/Sr24* each likely comprise separate genes that are inherited as a linkage block due their presence on chromosomal segments that were introgressed into wheat from alien grass species.

Pathotype distribution determines varietal response

Long-term nation-wide annual surveys of the virulence of the cereal attacking rust pathogens have been critical in understanding and predicting the responses of cereal varieties to rust diseases and providing direction for resistance breeding. The separation of the eastern and western Australian cereal belts, the common movement of rusts from west to east, and the less common movement of rusts from east to west, have resulted in some pathotypes (and hence virulences) being restricted to eastern Australia.

At present, there is little difference in the pathotypes of stem rust that occur across Australia, and for this reason a single national stem rust response rating is provided for all varieties.

With stripe rust, virulences for the resistance genes *Yr17*, *Yr27*, *YrJ* (in triticale only) and *YrT* (in triticale only) occur only in eastern Australia. For this reason, separate ratings are provided for each variety for eastern and Western Australia. Virulence for two further resistance genes, *Yr4* and *Yr33*, has been detected in eastern Australia in recent years in the pathotypes 198 E16 A+ J+ T+ 17+ (“198”) and 239 E237 A- 17+ 33+ (“239”), respectively. An additional column has been added to **Table A-1** to indicate the impact, if any, of these pathotypes. It should be noted that while “198” has increased rapidly in frequency in eastern Australia in the 2019 and 2020 seasons, that of “239” has remained very low.

The most significant changes in rust response ratings between eastern and Western Australia in recent years has been due to a series of changes in the pathotypes of wheat leaf rust in Australia and the movement of several pathotypes from the eastern grains belt to WA. Changes to the varietal ratings in the eastern States have been from the occurrence of two new wheat leaf rust pathotypes: 76-3,5,7,9,10,12,13 +Lr37 (2013) and 104-1,3,4,6,7,8,9,10,12 +Lr37 (2014). These pathotypes have introduced virulence combinations that have altered the leaf rust resistance ratings of many varieties. The introduction of three wheat leaf rust pathotypes to Western Australia from the eastern states in 2013 (pathotype 76-1,3,5,7,9,10,12 +Lr37), 2015 (pathotype 104-1,3,4,6,7,8,10,12 +Lr37), and in 2017 (104-1,3,4,5,7,9,10,12 +Lr37) shifted the leaf rust response of many varieties in WA towards increased susceptibility. The primary change in the consensus ratings has been through the introduction of virulences for *Lr13* and *Lr27+31* to Western Australia. Varieties affected include: Chara, Corack, Emu Rock, Mace, Wallup and Wyalkatchem. Pathotype 104-1,3,4,6,7,8,10,12 +Lr37 combines virulence for *Lr13*, *Lr27+31* and *Lr37*, and has rendered varieties carrying one or more of these resistances more susceptible in both eastern Australia and WA.

The complementary ASR leaf rust resistance genes *Lr27+31* have been used in Australian wheat breeding since Gatcher was released in 1969 (Park & McIntosh 1994). In addition to conferring resistance to leaf rust, gene *Lr27* is associated with the durable APR stem rust resistance gene *Sr2* and *Lr31* with the non-durable APR leaf rust resistance gene *Lr12* (Singh et al., 1999). Virulence for *Lr27+31* was first detected in the early 1970s and then became very common, and but was displaced after 1990 by the buildup of an exotic leaf

rust pathotype avirulent for this resistance that was first detected in 1984 (Park et al 1995). We showed that virulence for *Lr27+31* was completely associated with virulence for the APR gene *Lr12*, and that the ASR gene *Lr31* and APR gene *Lr12* are likely one and the same (Singh et al. 1999). Virulence for *Lr27+31* was not detected again until 2014, with the appearance of pathotype 104-1,3,5,6,7,10,12 +Lr37, and is now once again common not only in eastern Australia but also WA.

Virulence for resistance gene *Lr24* was first detected in eastern Australia in 2000 (Park et al. 2002). It has been detected in all but four years since then. The frequency of virulence for *Lr24* in eastern Australia has remained low since 2015 (less than 7%), and has not been detected to date in 2020, and for this reason a single national rating for leaf rust response that does not take into consideration virulence for *Lr24* was assigned by the 2019 NVT panel. Eastern Australian Growers of all varieties carrying *Lr24* are advised nonetheless to monitor crops for leaf rust closely.

Acknowledgements

The national wheat rust disease assessments were conducted by cereal plant pathologists across Australia (Andrew Milgate, Steven Simpfendorfer, Grant Hollaway, Hugh Wallwork, Manisha Shankar). Input from wheat breeders is also acknowledged, with special thanks going to AGT and GxE Crop Research. NVT data were compiled by staff at the National Variety Trials.

Table 1 Response descriptors for the rust diseases

Response	Description
R	highly resistant: occasional symptoms of infection including necrotic flecks; no sporulation
RMR	resistant: symptoms evident and usually with necrosis and chlorosis, limited sporulation, and affected leaf area up to 15%
MR	moderately resistant: evidence of sporulating areas on the leaf surface with some chlorosis and necrosis, and affected leaf area up to 30%
MRMS	intermediate: restricted sporulating areas with some chlorosis, and affected leaf area up to 50%
MS	moderately susceptible: freely sporulating lesions and affected leaf area up to 70%
MSS	moderately susceptible to susceptible: freely sporulating lesions with leaf area affected up to 90%
S	susceptible: abundant sporulation across the whole leaf surface; leaf area affected up to 100%; some chlorosis and necrosis evident
SVS	susceptible to very susceptible: abundant sporulation across the leaf surface; leaf area affected up to 100%; limited chlorosis
VS	highly susceptible: abundant sporulation across the whole leaf area with no evidence of chlorosis or necrosis; 100% leaf area affected

* Genes in **bold** face are still effective against all current pathotypes in Australia

** ASR= All Stage Resistance, APR= Adult Plant Resistance

^ indicates the variety may be more susceptible to virulent pathotypes that occur in eastern Australia at a low frequency

+ or ? indicate the presence of an uncharacterised resistance gene

Het indicates a mixed (heterogeneous) response to the disease or for the presence of a resistance gene

P indicates a provisional rating that requires further testing to validate

indicates response to stripe rust pathotype 198 E16 A+ J+ T+ 17+

indicates response to stripe rust pathotype 239 E237 A- 17+ 33+
